# Path Planning for Dynamic Graphs using A\* on GPU

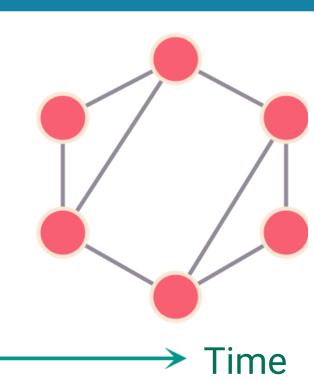

#### Abstract

- A\* is one of the widely used path planning algorithms applied in a diverse set of problems in robotics and video games.
- Zhou and Zeng [1] proposed a parallel variant of A\* for GPU, which keeps multiple priority queues to find the optimal path in a static graph (static A\*).
- Here we present A\* for dynamic graphs (dynamic A\*) on GP-GPUs which achieves 2x-7x speedup than static A\* on the SNAP dataset [2]

## **Dynamic Graphs**

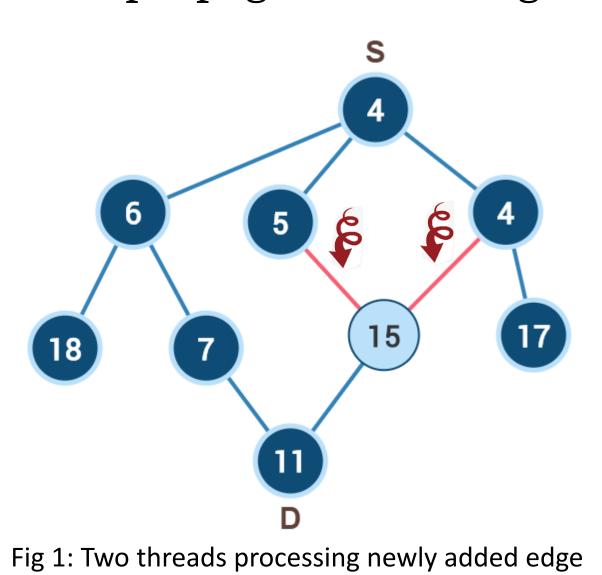

## Dynamic A\*: Insertion of edges

- Newly added edges can alter the optimal path.
- To find the new optimal path instead of executing A\* from scratch, we propagate the change to the affected nodes of the graph.

(shown in red)

#### Pseudocode!

- 1. For edges(u, v) inserted, add node v to update\_list, if f(v)<sub>new</sub> < f(v)<sub>old</sub>.
- 2. While update\_list not empty:
- a. Extract node n from update\_list.
- b. For each child of n:
- i. lock(child)
   ii. if f(child)<sub>new</sub> < f(child)<sub>old</sub>, add child
   to update\_list.
- iii. unlock(child)

f(v): cost of node v = g(v) + h(v)

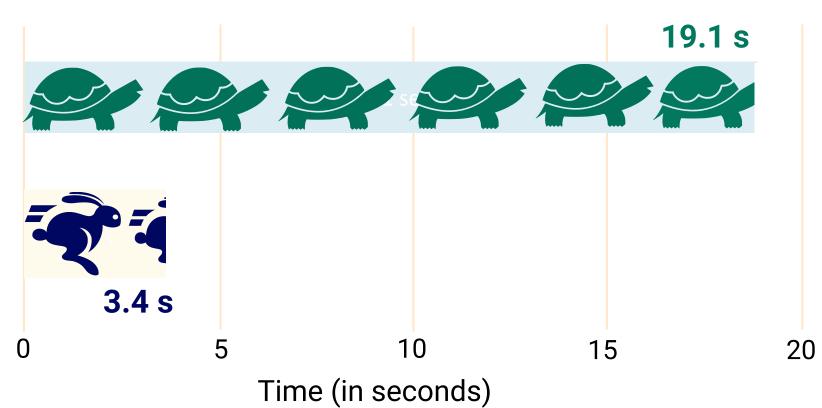

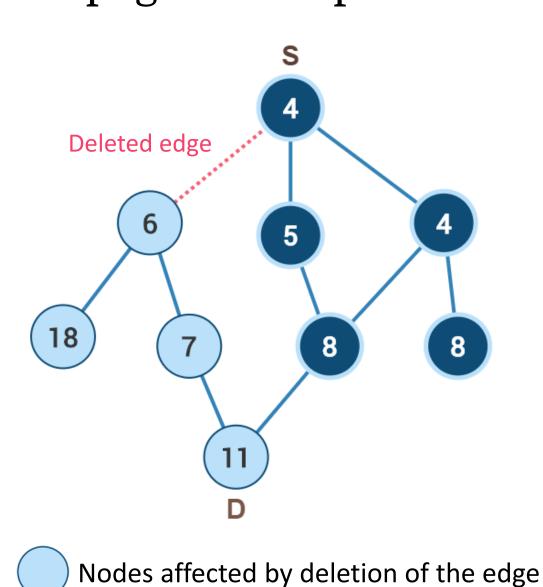

Fig 2: Execution time of static A\* and dynamic A\*(only insertions) on graph Wiki-Talk

## Dynamic A\*: Deletion of edges

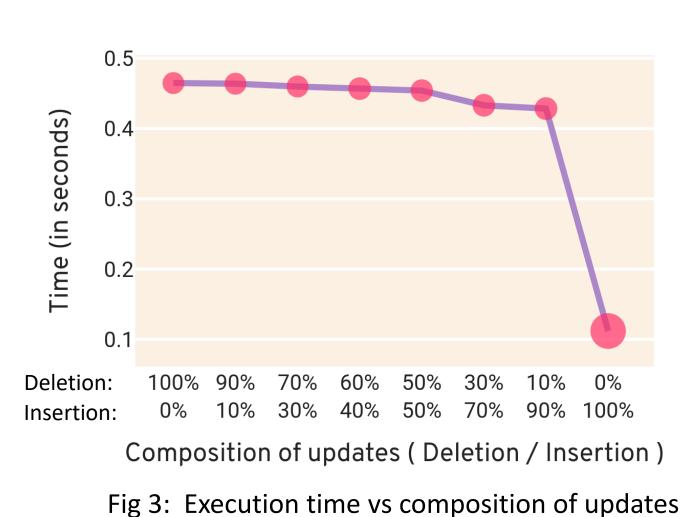

- Deleting only that edge which belongs to the optimal path can create a new optimal path.
- For all such affected nodes recompute the cost and select the neighbour with the least cost.
- Propagate the updated cost to all the affected nodes.

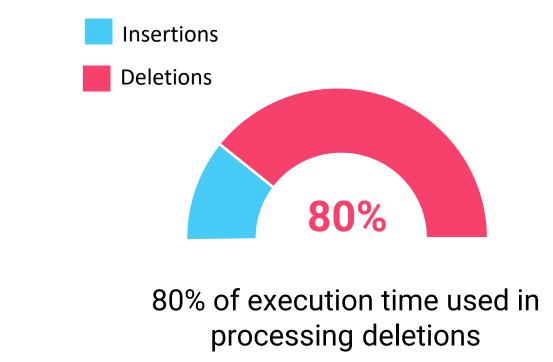

#### Pseudocode!

- For each deleted edge u → v:
   a. Compute f(v) from the neighbours of v.
   b. Add v to update\_list.
- 2. While update\_list is not empty:
  - a. Extract node n from update\_list.b. For each child of n such that
  - optimal\_parent(child) = **n**:
  - i. If f(child) > f(child)<sub>new</sub> then compute cost of child from each of its neighbour and add it to update\_list.

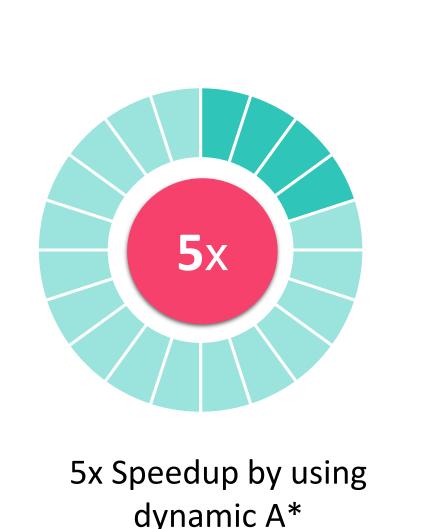

optimal\_parent(v): neighbour of node v with least f(v)

### Dynamic A\*: Fully Dynamic

- The update contains both insertion and deletion of edges.
- Propagate insertions and deletions of edges separately.
- Performs better than re-executing static A\* algorithm after each update.

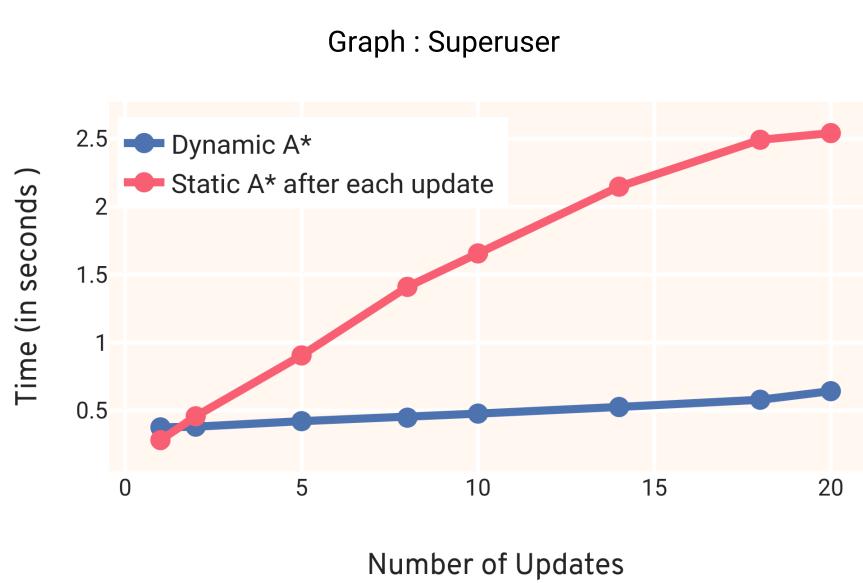

Fig 4: Execution time vs number of updates In the graph

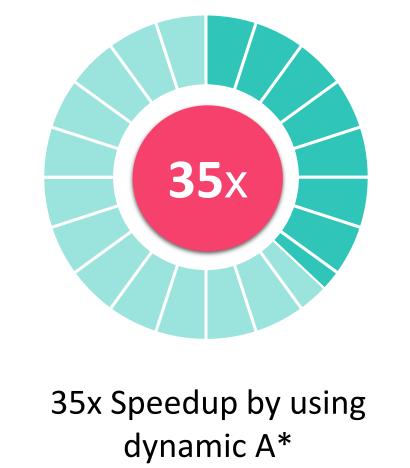

#### Results

The below table shows execution time (in seconds) and speedup of dynamic A\* compared to re-executing static A\* every time.

No.	Graph	Edges	Queries	Dynamic A*	Static A*	Speedup
1	Live Journal	34,681,189	10	6.01	33.93	5x
2	Wiki Talk	7,833,140	10	12.24	24.84	2x
3	Ask Ubuntu	964,437	10	0.25	1.31	5x
4	YouTube	2,987,624	10	0.81	5.78	<b>7</b> x
5	Math Overflow	506,550	10	0.09	0.67	7x
6	Live Journal	34,681,189	100	11.41	424.06	37x

#### **Applications**

1. We have applied dynamic A\* on energy efficient routing protocol (EERP) and achieved 35x speedup from static A\*.

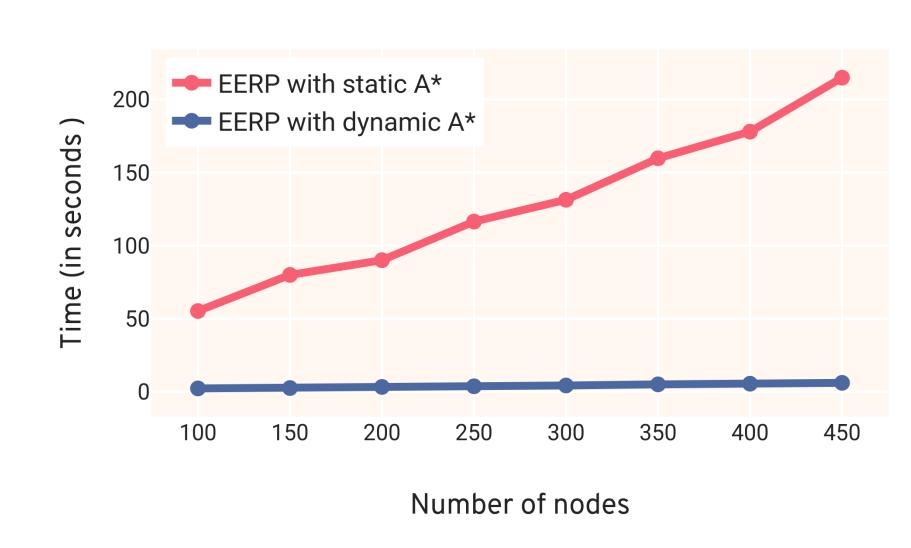

Fig 5: Comparison b/w static A\* and dynamic A\* on EERP algorithm

2. On applying dynamic A\* for pathfinding in the maze, we achieved 8x speedup.

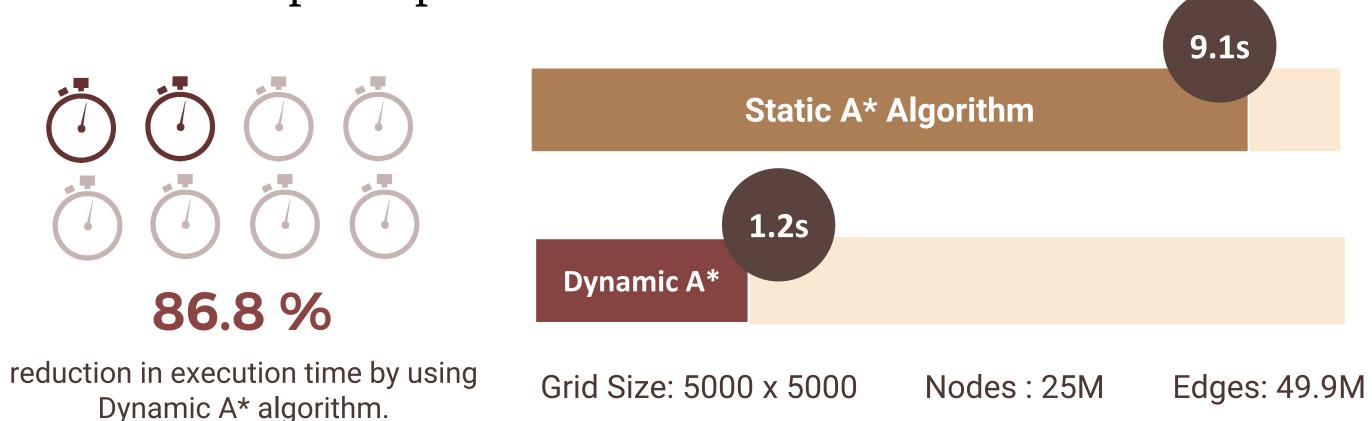

Fig 6: Comparison b/w static A\* and dynamic A\* on solving 5000 x 5000 maze

Time in seconds
